

Building an optimized site

DocsForge includes the `minify` plugin by default. It compresses HTML, CSS, and JavaScript at build time.

What's optimized automatically

The `minify` plugin strips:

- Whitespace and newlines from HTML
- HTML comments
- Optional attribute quotes
- CSS and JavaScript whitespace

This runs on every build with no configuration needed.

Image optimization

For best results, optimize images before adding them to your docs:

```
# Using pngquant for PNGs
pngquant --quality=70-90 docs/assets/images/*.png

# Using cwebp for WebP conversion
cwebp -q 80 image.png -o image.webp
```

Recommended formats

Format	Best for	Size
SVG	Logos, icons, diagrams	Smallest
WebP	Photos, screenshots	~25% smaller than PNG
PNG	Screenshots with transparency	Lossless
JPEG	Photos without transparency	Good compression

Image sizing guidelines

- Keep images under 200KB when possible
- Use `width` attribute to constrain large images: `![Alt](img.png){ width="400" }`
- Lazy loading is enabled by default — no configuration needed

Privacy plugin (external assets)

The `privacy` plugin downloads and caches external assets (like Google Fonts) during the build. This means:

- No CDN calls at runtime
- Faster page loads
- Works offline
- Better privacy for your users

Runs automatically on every build.

Build output

```
docsforge build
```

The `site/` directory contains the optimized static site, ready for deployment.

Performance checklist

- ☐ Images optimized (WebP preferred, SVG for icons)
- ☐ No external assets (privacy plugin handles this)
- ☐ Minification enabled (default)
- ☐ Cache-busting hashes in filenames (default)
- ☐ Service worker for offline use (default)
- ☐ Lazy loading for images (default)

Measuring performance

Use these tools to check your site's performance:

- [Google PageSpeed Insights](#)
- [Lighthouse](#) (built into Chrome DevTools)

- [WebPageTest](#)

A well-optimized DocsForge site typically scores 90+ on all Lighthouse metrics.
